

**Nitrogen and Phosphorus Load Estimates from Iowa Point Sources  
During the 1980-96 Hypoxia Task Force Baseline Period**

Prepared by the Iowa Department of Natural Resources:

Melinda McCoy, Adam Schnieders, Lindsay Mack, Courtney Cswercko, and Wendy Hieb

June 2018

## **Executive Summary**

The Hypoxia Task Force (HTF) 2015 goal framework includes an interim target to reduce nitrogen and phosphorus loading 20% by 2025 while continuing efforts to achieve the 45% reduction target by 2035. These targets are to be measured relative to the average Mississippi/Atchafalaya River Basin (MARB) nutrient loading to the Gulf of Mexico during the 1980-1996 “baseline” period. Given this and efforts to implement Iowa’s Nutrient Reduction Strategy (INRS), it will be important to have the ability to track point source progress in reducing nutrient loads from those loads present during the 1980-1996 baseline period.

In 2016, the Iowa Department of Natural Resources (Iowa DNR) began coordinating with the United States Geological Survey (USGS) in an effort to better understand historical nutrient loads from point sources in Iowa. The USGS shared a draft data set which contained annual total nitrogen (TN) and annual total phosphorus (TP) load estimates for Iowa point sources for the years 1992, 1997, and 2002 (hereinafter referred to as the “shared data set”). As described below, the Iowa DNR evaluated the 1992 annual nutrient loads and concluded that the shared data set could be used, with modification, to estimate baseline nutrient loads for Iowa point sources. Using the modified approach described below, 1992 annual TN and TP loads were estimated for Iowa’s major publicly-owned treatment works (POTWs), minor domestic wastewater dischargers (including POTWs and semipublic facilities), and industrial dischargers that provide biological treatment of process wastewater (BTP). These loads were then summed to provide the point source baseline TN and TP load estimates shown in Table 1.

**Table 1.** Iowa Point Source 1992 Annual Baseline TN and TP load estimates.

<b>Discharge Type</b>	<b>Total Nitrogen (tons)</b>	<b>Total Phosphorus (tons)</b>
Major POTWs	10,311	1,380
Minor Domestic Wastewater Dischargers	1,597	324
Industrial (major and minor with BTP)	1,262	683
Sum	13,170	2,386

### **Justification for Using 1992 as the Reference Point for the Baseline Nutrient Load Estimates**

The year 1992 was selected as the reference point for estimating baseline nutrient loads for Iowa point sources for three reasons. First, the shared data set includes actual discharger-specific monthly average or seasonal effluent flow data from 1992 for a large number of both domestic wastewater and industrial point source dischargers in Iowa. This flow data set is the earliest that is readily available during the 1980-1996 “baseline” period for a comprehensive universe of Iowa point source dischargers. Second, the year 1992 falls within the 1980-1996 “baseline” period associated with the HTF nutrient reduction targets. Third, based on a review of Iowa statewide monthly average precipitation totals for each year during the 1980-1996 period (Table 2), 1992 is a representative year in terms of average rainfall for the period as a whole. This is important since precipitation levels influence point source flows due to inflow and infiltration, and effluent flows, in turn, affect nutrient loads. Both the wettest and third driest years on state record (1873-2017) occurred during the 1980-1996 period. Yearly totals based on statewide monthly average precipitation records during the 1980-1996 period ranged from 21.65 inches (1988) to 48.22 inches (1993). The average of these yearly totals was 34.56 inches. The yearly total for 1992 was 36.66 inches, which is only 2.1 inches greater than the 1980-1996 average, and falls within the mid-range of yearly totals during 1980-1996 period.

**Table 2.** Iowa Statewide Average Precipitation (inches), 1980-1996.

\*Rank No. 1 represents the wettest year on state record between 1873 and 2017.

## Summary of Nutrient Load Data Set Shared by USGS

The shared data set included facility information, effluent flows, TN and TP effluent concentrations, and annual TN and TP load estimates for major and minor domestic and industrial wastewater dischargers in Iowa for the years 1992, 1997, and 2002. Data sources, methods, and load calculation procedures are detailed in Maupin and Ivahnenko (2011). Briefly, nutrient loads were derived only for those facilities with actual measured effluent flow data. Effluent flow and nutrient concentration data were obtained primarily from the United States Environmental Protection Agency's (USEPA) permit compliance system (PCS) database, with some data obtained directly from states. Where TN and TP effluent concentrations were not available, concentrations were estimated using a hierarchy of "typical pollutant concentrations" (TPCs). Factors considered in deriving the TPCs included: standard industrial classification (SIC) code, major river basin (Mississippi (MRB3) or Missouri (MRB4)), season (n=4), and effluent flow class (n=5).

## Major POTWs

### ***Evaluation of the Shared Data Set for Major POTWs***

Since major POTWs are prioritized over minor domestic wastewater dischargers in the INRS, the Iowa DNR first focused on major POTWs when evaluating the 1992 annual nutrient load estimates available in the shared data set.

For a subset of major POTWs, monthly average effluent flows from 1992 in the shared data set were compared with monthly average effluent flows from 1992 available in Iowa DNR's own database. The effluent flows in the shared data set matched those available in the Iowa DNR's database. Since flow data within the Iowa DNR's database were available for more POTWs in the year 1997 than 1992, monthly average effluent flows from 1997 in both data sets were also compared for a subset of major POTWs to provide further confidence regarding the agreement between both flow data sets.

In regards to TN and TP effluent concentrations, the 1992 annual nutrient load estimates for major POTWs in the shared data set were derived using TPCs for sewerage systems (SIC code 4952) based on major river basin, season, and effluent flow class (Table 3). The Iowa DNR compared the TPCs used in the shared data set with TPCs used in other nutrient load estimation efforts for sewerage systems (Table 4). Comparisons were made with Pait (1993), Tetra Tech (1999), USEPA (2007), USEPA's Discharge Monitoring Report (DMR) loading tool (2018), and the INRS (2013).

Pait (1993), Tetra Tech (1999), and the USEPA (2007) derived TPCs for TN and TP based on treatment level (i.e., primary, secondary, tertiary). The nutrient model used in the USEPA's DMR loading tool (2018) derives TPCs for POTWs not likely to have additional treatment for nutrients, and effluent flow class is considered in deriving these TPCs. The INRS (2013) included point source nutrient load reduction estimates based on the assumption that current TN and TP effluent concentrations are equivalent to that found in typical domestic sewage (25 mg/L and 4 mg/L, respectively) and that biological nutrient removal (BNR) technology can achieve TN and TP effluent concentrations of 10 mg/L and 1 mg/L, respectively.

**Table 3.** Summary of TPCs for Sewerage Systems Used in Data Set Shared by USGS.

Factors Considered in Deriving TPCs			TPC Statistics (mg/L)					
River Basin	Flow Class*	Season**	TN (min)	TN (max)	TN (avg)	TP (min)	TP (max)	TP (avg)
MRB3	≤1 MGD**	n = 4	2.6	21.6	13.2	0.8	1.9	1.5
	>1-≤5 MGD	n = 4	8.3	12.1	10.6	0.6	0.7	0.6
	>5 MGD	n = 4	12.0	19.5	14.2	0.6	0.7	0.6
MRB4	≤1 MGD**	n = 4	12.5	20.5	16.9	0.4	1.9	0.9
	>1-≤5 MGD	n = 4	8.0	11.9	10.3	1.7	2.5	2.0
	>5 MGD	n = 4	14.2	22.0	18.0	1.5	1.8	1.7

\*The ≤1 MGD flow class includes three subsets: ≤0.05 MGD, >0.05 to ≤0.2 MGD, and >0.2 to ≤1 MGD

\*\*Seasons include spring (Mar-May), summer (Jun-Aug), fall (Sep-Nov), and winter (Dec-Feb)

**Table 4.** Summary of TPCs for Sewerage Systems Used in Other Nutrient Load Estimation Efforts.

TPC Source	Factors Considered in Deriving TPCs		TPC (mg/L)	
	Treatment Type	Flow Class	TN	TP
INRS, 2013	Typical Domestic Sewage		25.0	4.0
Pait, 1993	Primary		15.1	13.0
Pait, 1993			11.2	7.0
TetraTech, 1999	Secondary		11.2	2.0
EPA SAB, 2007			15	4
EPA DMR, 2018	POTWs not likely to have additional treatment for nutrients	all	13.343	2.439
		≤1 MGD	14.436	2.422
		>1-≤5 MGD	12.75	2.599
		>5 MGD	13.586	2.039
Pait, 1993	Tertiary		5.6	3.5
TetraTech, 1999			5.6	0.8
EPA SAB, 2007			11.2	2.0
INRS, 2013	Achievable with BNR		10.0	1.0

The TPCs used to derive the 1992 annual nutrient load estimates in the shared data set were also compared with Iowa-specific TPCs for major POTWs (Table 5). The Iowa-specific TPCs were derived using recent nutrient effluent concentration data now available through implementation of the INRS. More specifically, the TPCs were derived using actual monthly average TN and TP effluent concentrations from calendar year 2016 for 54 major POTWs. The monthly average TN and TP effluent concentrations were divided into one of three flow class categories (<1 MGD, 1-5 MGD, and >5 MGD) based on the monthly average effluent flow associated with the concentration value. The Iowa-specific TPCs reflect the average TN and TP effluent concentrations for each of these flow classes. It should be noted that as more effluent concentration data become available in the future, opportunities may exist to further refine these TPCs in consideration of additional factors such as secondary treatment technology type (aerated lagoon, activated sludge, etc.).

Though the Iowa-specific TPCs are not based on nutrient effluent concentration data from the 1980-1996 “baseline” period, they should be considered when evaluating the TPCs used to derive the 1992 annual nutrient load estimates in the shared data set for three reasons. First, there is a general lack of TN and TP effluent concentration data from Iowa domestic wastewater dischargers during the 1980-1996 “baseline” period. Second, the majority of Iowa POTWs continue to employ secondary treatment without additional treatment specifically intended to remove nutrients. Third, as reflected in Table 5, large sample sizes support the Iowa-specific TPCs (54 major POTWs, weekly sampling). Fourth, as previously noted, yearly rainfall totals based on statewide

monthly average precipitation records during the 1980-1996 period ranged from 21.65 inches (1988) to 48.22 inches (1993). The average of these yearly totals was 34.56 inches. As shown in Table 6, the yearly total for 2016 was 38.76 inches, which is only 4.2 inches greater than the 1980-1996 average.

**Table 5.** Iowa-specific TPCs for Major POTWs.

Statistic	Flow Class	Sample Size	TPC (mg/L)	
			TN	TP
Average	<1 MGD	216	15.8	3.2
	1-5 MGD	322	13.3	2.6
	>5 MGD	102	24.7	2.9

**Table 6.** Iowa Statewide Average Precipitation (inches), 2016.

Year	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	ANN	RANK* (1873-2017)
2016	0.64	0.96	2.46	3.26	4.53	3.69	5.88	6.05	6.19	2.10	1.45	1.55	38.76	19
AVG 1980-1996	0.89	0.81	2.18	3.13	4.30	4.63	4.56	4.37	3.61	2.43	2.34	1.32	34.56	

\*Rank No. 1 represents the wettest year on state record between 1873 and 2017.

In making the TPC comparisons detailed above, it was noted that the TPCs in the shared data set were generally less than those used in EPA's DMR loading tool and less than the Iowa-specific TPCs. This was particularly true for TN in the middle flow class and for TP in all flow classes, where the TPCs in the shared data set were closer to levels anticipated for POTWs employing tertiary treatment.

To further evaluate the TPCs in the shared data set, 1992 annual nutrient load estimates for 51 Iowa major POTWs were derived using the discharger-specific monthly average effluent flows from 1992 and three different concentration assumptions. These assumptions used: a) the TPCs in the shared data set, b) the Iowa-specific TPCs, and c) discharger-specific actual monthly average TN and TP effluent concentrations from 2016. Where only seasonal average effluent flows were available, the seasonal flow was applied to each month during the season. The 51 discharger-specific loads were then summed for each parameter and calculation method. The results are shown in Table 7 below. As would be anticipated, the annual load sums derived using the Iowa-specific TPCs are similar to the annual load sums derived using the discharger-specific actual monthly average TN and TP effluent concentrations from 2016. In comparison, the annual load sums derived using the TPCs in the shared data set are approximately 39% lower for TN and 76% lower for TP. It can be assumed that the TPCs in the shared data set are the reason for these lower load estimates since the same effluent flows were used in all three calculation methods.

**Table 7.** Comparison of 1992 Annual TN and TP Load Sums (lbs) for 51 Major POTWs Derived Using 1992 Monthly Average Effluent Flows and Three Different Concentration Assumptions.

Parameter	TPCs from Data Set Shared by USGS	Iowa-specific TPCs	Discharger-specific 2016 Monthly Avg Effluent Concentrations
TN	6,691,587	10,962,162	10,984,987
TP	343,644	1,451,146	1,459,603

#### ***Derivation of 1992 Annual Baseline Nutrient Load Estimates for Major POTWs***

Based on the above evaluation, it was concluded that baseline TN and TP loads for Iowa's major POTWs would be best estimated using the effluent flows from 1992 in the shared data set and the Iowa-specific TPCs. 1992 annual baseline TN and TP loads were estimated for 106 major POTWs (listed in Appendix A). These include the 103 major POTWs listed in the 2017 INRS, the City of Cascade which was recently classified as a major POTW, and two major POTWs (City of Ankeny and Iowa City (North)) that are closed but now send their wastewater to other major POTWs listed in the 2017 INRS.

For each major POTW, monthly TN and TP loads were derived in the following manner. The monthly average effluent flow was multiplied by the corresponding Iowa-specific TPC, by the number of days in the month, and by a conversion factor of 8.3453. For the cities of Carlisle and Jesup (South), 1992 monthly average effluent flows

were not available in the shared data set but were available for 1997 and 2002. As such, these 1997 and 2002 effluent flows were used instead. For four major POTWs (cities of Ames, Knoxville, New Hampton, and Storm Lake), no effluent flow data was available in the shared data set. For these four POTWs, monthly average effluent flows for 1992 were estimated by applying a percentage (17.96%) to the monthly average effluent flows for these dischargers in 2016. This percentage reflects the percent difference between the 1992 and 2016 total annual flows for the subset of POTWs with both 1992 and 2016 effluent flows. Where only seasonal average effluent flows were available, the seasonal flow was applied to each month during the season.

Once monthly loads were derived for each of the 106 major POTWs, the monthly loads were summed to derive an annual load for 1992 for each of the POTWs. The 1992 annual loads for each POTW were then summed to provide 1992 annual baseline TN and TP load estimates shown in Table 8. The 1992 total annual flow estimate from all 106 major POTWs is also shown in Table 8.

**Table 8.** 1992 Annual Flow and Baseline TN and TP Load Estimates for Major POTWs.

Point Source Discharge Type	Flow	Total Nitrogen		Total Phosphorus	
	billion gallons	lbs	tons	lbs	tons
Major POTWs	115.48	20,622,402	10,311	2,759,974	1,380

### Minor Domestic Wastewater Dischargers

#### *Evaluation of the Shared Data Set for Minor Domestic Wastewater Dischargers*

A review of the shared data set revealed that 1992 annual nutrient load estimates were only available for approximately half of the minor domestic wastewater dischargers that existed in Iowa in 1992. Further, based on evaluation of current average wet weather (AWW) design flows, minor domestic wastewater dischargers represent approximately 11% of the total flow from all point sources in Iowa. For these reasons, the 1992 annual TN and TP load estimates for those minor domestic wastewater sources that were available in the shared data set were not used directly in deriving the baseline nutrient load estimates for all minor domestic wastewater dischargers. Rather, the modified approach described below was used to estimate baseline nutrient loads for this category of point sources.

#### *Derivation of 1992 Annual Baseline Nutrient Load Estimates for Minor Domestic Wastewater Dischargers*

There are currently 104 major POTWs representing a total AWW design flow of 650.98 MGD. Additionally, there are currently 909 minor domestic wastewater dischargers (including minor POTWs and semi-public facilities) representing a total AWW design flow of 147.88 MGD. These total AWW design flows were adjusted to the number of major POTWs and minor domestic wastewater dischargers that existed in 1992. The resulting 1992-adjusted total AWW design flows for major POTWs and minor domestic wastewater dischargers were 644.72 MGD and 135.27 MGD, respectively. The ratio of the 1992-adjusted total AWW design flow for minor domestic wastewater dischargers to the 1992-adjusted total AWW design flow for major POTWs is 20.98%.

The 20.98% ratio was then applied to the 1992 total annual flow for major POTWs shown in Table 7 above (115.48 billion gallons) in order to estimate a 1992 total annual flow for the minor domestic wastewater dischargers that existed in 1992. This resulting flow (24.23 billion gallons) was then multiplied by the Iowa-specific TPCs for the <1 MGD flow class (15.8 mg/L TN and 3.2 mg/L TP) to derive the 1992 annual TN and TP load estimates for minor domestic wastewater dischargers that are shown in Table 9 below.

**Table 9.** 1992 Annual Flow and Baseline TN and TP Load Estimates for Minor Domestic Wastewater Dischargers.

Point Source Discharge Type	Flow	Total Nitrogen		Total Phosphorus	
	billion gallons	lbs	tons	lbs	tons
Minor Domestic Wastewater Dischargers	24.23	3,194,596	1,597	647,007	324

## Industrial Dischargers with BTP

### *Evaluation of the Shared Data Set for Industrial Dischargers with BTP*

The 2017 INRS identifies 32 major and minor industrial dischargers that provide biological treatment of process wastewater (BTP). Those major industrial dischargers identified on the 2017 INRS as not providing BTP are not included in the baseline derivation effort at this time. This is due in part to the complexity in determining baseline loads for dischargers like power plants where the “net increase” compared to background nutrient loads is the load of interest for tracking purposes. In addition, design flow information is not available for most major industrial dischargers who do not provide BTP.

Eight of the 32 industrial dischargers with BTP did not exist in 1992. For the remaining 24 industrial dischargers, the Iowa DNR identified those outfalls with process wastewater receiving biological treatment and then reviewed the shared data set to determine whether 1992 annual nutrient load estimates were available for these outfalls. Based on this review, 13 industrial dischargers were identified that have 1992 annual nutrient load estimates in the shared data set. As with the major POTWs previously described, the load estimates in the shared data set were derived using actual measured discharger-specific effluent flow data from 1992 and TPCs. The effluent flows were either monthly averages or seasonal averages. Likewise, TPCs were applied on a monthly or seasonal basis.

To evaluate the TPCs underlying the 1992 annual nutrient load estimates in the shared data set, the TPCs were compared with recent nutrient effluent concentration data now available through implementation of the INRS. For each of the aforementioned 13 industrial dischargers, the TPCs used for the discharger were averaged and then compared to recent discharger-specific long-term average (LTA) concentrations for TN and TP. With one exception, the LTAs reflect the average of daily TN or TP effluent concentrations available from September 2013 to April 2017. For Cargill, Inc., the LTAs reflect the average of daily TN or TP effluent concentrations available from December 2017 to February 2018.

A similar comparison was performed for the effluent flows underlying the 1992 annual nutrient load estimates in the shared data set. Each discharger’s 1992 monthly (or seasonal) average effluent flows were averaged and then compared to discharger-specific LTA effluent flows. Each discharger-specific LTA effluent flow was calculated by averaging the discharger’s monthly average effluent flows from September 2013 to April 2017.

Based on the results of the aforementioned comparison (Table 10), the effluent flows underlying the 1992 annual nutrient load estimates in the shared data set appear to be reasonable for use in deriving baseline TN and TP loads for the 13 industrial dischargers. However, in most instances, the total phosphorus TPC average used for a given discharger was lower (often significantly lower) than the recent discharger-specific LTA concentration for TP. In most instances, the total nitrogen TPC average used for a given discharger was either significantly lower or significantly higher than the recent discharger-specific LTA concentration for TN.

**Table 10.** Comparison of effluent flows and TPCs underlying the 1992 annual nutrient load estimates in the data set shared by USGS with recent discharger-specific LTA effluent flows and TN and TP concentrations.

#### ***Derivation of 1992 Annual Baseline Nutrient Load Estimates for Industrial Dischargers with BTP***

A multi-faceted approach based on data availability was used to derive the 1992 annual baseline TN and TP loads shown in Table 11 below for the industrial dischargers with BTP. Individual discharger-specific baseline TP and TP loads are provided in Appendix B.

For the 13 industrial dischargers identified in Table 10, monthly TN and TP loads were derived in the following manner (referred to as a Type 1 estimate in Appendix B). The monthly average effluent flows from 1992 in the shared data set were multiplied by the recent discharger-specific LTA concentrations for TN and TP shown in Table 10, by the number of days in the month, and by a conversion factor of 8.3453. As previously described, the LTA concentrations reflect the average of daily TN and TP effluent concentrations from September 2013 to April 2017, except in the case of Cargill, Inc. Where only seasonal average effluent flows were available from 1992, the seasonal flow was applied to each month during the season. The monthly loads were then summed to derive an annual load for each of the 13 dischargers.

Note that although the LTA concentrations for the 13 dischargers are reflective of more recent data, they were used to derive the baseline loads since actual measured discharger-specific TN and TP concentrations are not available for 1992. Additionally, the LTA concentrations are believed to be more representative of concentrations that would have existed in 1992 than the TPCs used to derive the 1992 annual nutrient loads in the shared data set. This conclusion is based on the TPC evaluation previously described and the discharger-specific nature of the LTA concentrations.

For 11 industrial dischargers, effluent flows from 1992 were not available in the shared data set. For 9 of these dischargers, annual baseline TN and TP loads were derived by multiplying LTA loads for TN and TP by 365 days per year (referred to as a Type 2 estimate in Appendix B). The LTA loads reflect the average of daily TN and TP effluent loads available from September 2013 to April 2017. In three cases (Monsanto, Gelita, and Ajinomoto Heartland), only more recent daily effluent loads were available so these were used to calculate the LTA.

For one of the aforementioned 11 industrial dischargers (Pinnacle Foods Group), daily TN and TP effluent loads were not available in the facility's discharge monitoring reports. Therefore, a LTA effluent flow was derived by averaging daily effluent flows for the discharger from September 2013 to April 2017. The LTA effluent flow was multiplied by the average of the daily TN and TP effluent concentrations from September 2013 to April 2017. These results were then multiplied by a conversion factor of 8.3453 and by 365 days per year to derive the annual TN and TP baseline loads (referred to as a Type 3 estimate in Appendix B).

For one of the aforementioned 11 industrial dischargers (Northern Natural Gas – Redfield), no TN or TP effluent concentration data were available. Since the effluent from this facility is not anticipated to be high in TN or TP,

the INRS concentration targets of 10 mg/L for TN and 1 mg/L for TP were used to derive the annual baseline loads. These concentrations were multiplied by the average of combined daily effluent flows from outfalls 001 and 002 from September 2013 to April 2017. These results were then multiplied by a conversion factor of 8.3453 and by 365 days per year to derive the annual TN and TP baseline loads (referred to as a Type 4 estimate in Appendix B).

The 1992 annual baseline TN and TP load estimates shown in Table 11 reflect the sum of the annual loads for each of the 24 industrial dischargers described above. For the remaining 8 industrial dischargers that did not exist in 1992, baseline TN and TP loads were set equal to zero (referred to as a Type 5 estimate in Appendix B).

**Table 11.** 1992 Annual Baseline TN and TP Load Estimates for Major and Minor Industrial Dischargers with Biological Treatment of Process Wastewater.

Point Source Discharge Type	Total Nitrogen		Total Phosphorus	
	lbs	tons	lbs	tons
Industrial (major and minor with BTP)	2,523,018	1,262	1,365,945	683

## Conclusions

The 1980 -1996 point source annual baseline TN and TP load estimates were derived using actual facility-specific effluent flows from 1992 where available and concentrations based on actual TN and TP effluent concentration data for Iowa point sources now available through implementation of the INRS.

Moving forward, the Iowa-specific TPCs derived under this effort may also be useful for estimating nutrient loads in future INRS annual reports for those major POTWs lacking TN and TP effluent concentration data (until such time as those data become available). Additionally, as additional data becomes available further refinement of these baseline estimates may be possible in the future.
